Secular trends in the prevalence of female genital mutilation/cutting among girls: a systematic analysis

Ngiasi-Bakwin Kandala, 1, 2 Martinsixtus C Ezejimofor, 1, 3 Olalekan A Uthman, 4 Paul Komba 1

ABSTRACT

Background Current evidence on the decline in the prevalence of female genital mutilation or cutting (FGM/C) has been lacking worldwide. This study analyses the prevalence estimates and secular trends in FGM/C over sustained periods (ie, 1990–2017). Its aim is to provide analytical evidence on the changing prevalence of FGM/C over time among girls aged 0–14 years and examine geographical variations in low-income and middle-income countries.

Methods Analysis on the shift in prevalence of FGM/C was undertaken using the Demographic Health Survey (DHS) and Multiple Indicator Cluster Survey (MICS) data sets from Africa and Middle East. A random-effects model was used to derive overall prevalence estimates. Using Poisson regression models, we conducted time trends analyses on the FGM/C prevalence estimates between 1990 and 2017.

Findings We included 90 DHS and MICS data sets for 208 195 children (0–14 years) from 29 countries spread across Africa and two countries in Western Asia. The prevalence of FGM/C among children varied greatly between countries and regions and also within countries over the survey periods. The percentage decline in the prevalence of FGM/C among children aged 0–14 years old was highest in East Africa, followed by North and West Africa. The prevalence decreased from 71.4% in 1995 to 8.0% in 2016 in East Africa. In North Africa, the prevalence decreased from 57.7% in 1990 to 14.1% in 2015. In West Africa, the prevalence decreased from 73.6% in 1990 to 25.4% in 2017. The results of the trend analysis showed a significant shift downwards in the prevalence of FGM/C among children aged 0–14 years in such regions and subregions of East Africa, North Africa and West Africa. East Africa has experienced a much faster decrease in the prevalence of the practice (trend=−7.3%, 95% CI −7.5% to −7.1%) per year from 1995 to 2014. By contrast, the decline in prevalence has been much slower in North Africa (trend=−4.4%, 95% CI −4.5% to −4.3%) and West Africa (trend=−3.0%, 95% CI −3.1% to −2.9%).

Conclusion The prevalence of FGM/C among children aged 0–14 years varied greatly between countries and regions and also within countries over the survey periods. There is evidence of huge and significant decline in the prevalence of FGM/C among children across countries and regions. There is a need to sustain comprehensive intervention efforts and further targeted efforts in countries and regions still showing high prevalence of FGM/C among children, where the practice is still pervasive.

Key questions

What is already known?

► Female genital mutilation or cutting (FGM/C) is highly concentrated in many low-income and middle-income countries (LMICs), particularly in Africa and Western Asia.

► The practice is viewed as a child abuse and a gross violation of children's and women's human rights, and is deemed unlawful by many countries and condemned by many organisations.

► It has devastating health consequences especially in terms of sexual, childbirth and mental health.

What are the new findings?

► The prevalence of FGM/C among children varied greatly between countries and regions and also within countries over the survey periods.

► We found evidence of significant decline in the prevalence of FGM/C in the last three decades among children aged 0–14 years in most of the countries and regions, particularly in East, North and West Africa.

► We show that the picture looks different in Western Asia, where the practice remains and affects the same age group.

What do the new findings imply?

► Evidence-based policies targeting socioeconomic and cultural support for children at risk of FGM/C in LMICs should be pursued vigorously.

► Appropriate research design, data collection and interventions containing religious and culturally sensitive elements remain an important public health policy priority.

INTRODUCTION

Recent estimates show that more than 200 million women and children around the world have undergone female genital mutilation and cutting (FGM/C). 1, 2 All the available data clearly refer to Africa and some Middle Eastern regions (including Iraq and Yemen) as areas where the practice is particularly most prevalent. Further findings from recent global research revealed the existence...
of such a practice in India, Indonesia, Israel, Malaysia, Thailand and the United Arab Emirates. Likewise, data from censuses and household and hospital records indicate that FGM/C constitutes a massive global health challenge in the sense that the high burden of FGM/C is clearly not confined to African and Middle Eastern countries, but extends to Europe and North and South America, especially as a result of migration. Incidents of FGM/C in the Western world are reported particularly from among asylum seekers and immigrants who have moved from regions where FGM/C is practised in order to settle in developed countries. Those who live in Africa have been affected by the practice as a result of socioeconomic and cultural issues. Thus, there is an emerging consensus that more than three million children in Africa are now at risk each year. In the present paper, we first offer an analytical picture of the estimates on the prevalence of FGM/C and identify secular trends limiting the study population to young girls aged 0–14 years in low-income and middle-income countries (LMICs).

The ultimate aim of this study is to inform decision-making processes and influence policy responses and public health intervention across many geographical regions and countries sharing the same socioeconomic and cultural backgrounds (such as unemployment level, level of education, and religion and ethnicity). The focus on these backgrounds is accounted for by a large number of selected regions in which well-tailed intervention programmes may be necessary to combat the practice. Accurate, up-to-date information on the prevalence of FGM/C among children is necessary for the development of national and international health policies for prevention of this practice, and would allow international public health policy-makers to assign sufficient priority and resources to its prevention. Although there are existing systematic reviews and reports on current prevalence estimates of FGM/C emanating from most international agencies, there are no pooled analyses of nationally representative survey data to examine the burden of FGM/C among children. Children aged 0–14 years were considered in this review partly because we wanted to understand whether the years-long campaigns on FGM/C among mothers have an impact on the reduction in the prevalence among their children, as children are relatively too young to understand what is best for themselves, compared with their adult women counterparts who, on personal, cultural and socioeconomic grounds, may engage in FGM/C. To fill this research gap, we therefore systematically gathered all survey data sets to assess (1) the contemporary prevalence estimates of FGM/C among children aged 0–14 years; (2) whether there is significant downward trend in the prevalence estimates or not; and (3) whether the burden of FGM/C among children varies across different geographical regions.

METHODS
Study design and data
We used data from the Demographic Health Survey (DHS) as developed by ICF International and the Multiple Indicator Cluster Survey (MICS) directed by Unicef. ICF International and Unicef provide technical assistance to countries conducting these national surveys. The two surveys are highly comparable and the technical teams developing and supporting them are in close collaboration. Both DHS and MICS surveys provide national representative data of households and estimates of adult women and children. This study examines the secular trends in the prevalence of FGM/C, focusing on countries where DHS/MICS data are available and on regions which significantly contribute to the global prevalence in FGM/C. Evidence suggests that international response has targeted such countries on account of the high prevalence observed in FGM/C practice or based on the number of women and girls at risk. This is the case despite evidence that prevalence may be low in those regions. Among other things, the DHS and MICS survey data sets give details about the health and wellbeing of children as well as women in countries affected by FGM/C practices. The surveys used a two-stage cluster and probability sampling design, with oversampling of certain categories of respondents. In the first stage, ‘clusters’ were selected from larger regional units within countries using sample weights techniques to obtain nationally representative estimates of indicators. Subsequently, the second stage of sampling, which involved the systematic sampling of households from the selected enumeration areas, was carried out. Data collection procedures and response rates for all DHS and MICS surveys were all published in each survey report.

The data sets on FGM/C are available in 29 countries spread across five United Nations subregions. Based on nationally representative samples of women and children, these surveys produce data that make it possible to calculate both the FGM/C prevalence and secular trends at both the national and subregional levels. In many of the targeted countries, more recent surveys have been produced. In order to provide an accurate and reliable estimate of the current FGM/C practices in these countries and regions, we searched the DHS and MICS databases (without restriction on language or date of publication) to look for FGM/C data on women and their daughters or children.

Statistical analysis
Meta-analysis of FGM/C prevalence estimates
Apparent prevalence estimates were computed using the total reported number of children who have undergone FGM/C in each country. The overall prevalence of FGM/C was pooled and compared by proportion across countries and regions using a meta-analysis technique. Before making such a move, we used the Freeman-Tukey variant of the arcsine square root transformed proportion suitable for pooling. This was necessary to stabilise
We also chose to meta-estimate one temporal trend from all the studies, accounting for correlations among multiple time intervals within studies. This indicates that the number of time points for which FGM/C was estimated varied across studies, and some of these included only one time point.

**RESULTS**

**Description of included survey data sets**

The countries, year of data collection and the survey characteristics are listed in Table 1. The surveys were conducted between 1990 and 2017. This analysis included 90 DHS and MICS data sets for 208 195 children (0–14 years) from 29 countries spread across Africa and two countries in Western Asia. Most of the surveys were DHS (n=55) and 35 were MICS. Most of the surveys were from West Africa (n=54), followed by East Africa (n=17), North Africa (n=10), Central Africa (n=6) and Western Asia (n=3) (Figure 1). The highest numbers of surveys were conducted in Nigeria (n=7), Senegal (n=7) and Mali (n=6).

**Variations in prevalence of FGM/C among children by country and geographical regions**

The prevalence of FGM/C among children and the 95% CIs from individual countries with a pooled estimate are shown in online supplementary figure 1 for Central Africa, online supplementary figure 2 for East Africa, online supplementary figure 3 for North Africa, online supplementary figure 4 for West Africa and online supplementary figure 5 for Western Asia, and are summarised in Table 1. In Central Africa, the FGM/C ‘annualized year average’ was highest for Chad (13.9%), followed by Central Africa Republic (3.0%) and Cameroon (0.7%). The FGM/C ‘annualized year average’ ranged from 2.0% (Kenya) to 67.0% (Eritrea) in East Africa; from 28.4% (Egypt) to 41.9% (Sudan) in North Africa.

**Secular trend in the prevalence of FGM/C among children aged 0–14 years**

Table 2 and figure 2 show the trends in the prevalence of FGM/C among children within the 0–14 age range who have been subjected to FGM/C. The percentage decline in the prevalence of FGM/C among children aged 0–14 years old was highest in East Africa, followed by North and West Africa. The prevalence decreased from 71.4% in 1995 to 8.0% in 2016 in East Africa. In North Africa, the percentage decreased from 57.7% in 1990 to 14.1% in 2015. In West Africa, the prevalence decreased from 73.6% in 1996 to 25.4% in 2017. This is to be contrasted with the picture in Western Asia, where the percentage increased only by 1.0% in 1997 and 15.9% in 2013.

The results of the trend analysis showed a significant shift downwards in the prevalence of FGM/C among children aged 0–14 years in such regions and subregions of East Africa, North Africa and West Africa. East Africa has experienced a much faster decrease in the prevalence of the practice (trend=−7.3%, 95% CI −7.5% to −7.1%)

AAPC, average annual percentage change.

per year from 1995 to 2014. By contrast, the decline in prevalence has been much slower in North Africa (trend=−4.4%, 95% CI −4.5% to −4.3%) and West Africa (trend=−3.0%, 95% CI −3.1% to −2.9%). However, in Western Asia, between 1997 and 2015, the prevalence of FGM/C among children aged 0–14 increased by +19.2% (95% CI +16.9% to +21.7%) per year. A non-statistically significant uptrend was also observed in Central Africa (trend =+0.2%, 95% CI −0.7% to +1.0%).

**DISCUSSION**

**Main findings**

We found that the prevalence of FGM/C among children varied greatly between countries and regions and also within countries over the survey periods. Specifically, West, East and North African countries, including Mali, Mauritania, Gambia, Guinea, Djibouti and Sudan, have pooled prevalence estimates well over 40%. These rates may be consistent with the influence of different predictors, including geographical mobility, socioeconomic and cultural factors acting at individual, family and tertiary levels.26 Our study found a huge and significant decline in the prevalence of FGM/C among children aged 0–14 years across countries and regions. This current evidence points towards the success of the national and international investment and policy intervention in the last three decades.27 One possible explanation in the decrease of FGM/C among young girls (0–14 years) could be the legal ban currently in place in most of these countries, where strong cultural and traditional influence may have acted as an effective deterrent as seen in the decline among these cohorts.28

Although there is clear evidence of significant decline in the prevalence among the population studied here (children aged 0–14 years old), the FGM/C risk factors still prevail, which potentially heightens the likelihood of reverse trend in some countries. These risk factors include lack of, or poor, education, poverty, gendered cultural forces, weak social fitness and continued perception of FGM/C as a potential marriage market activity.29–34 The health and socioeconomic consequences of FGM/C coupled with its risk factors may mean...
growing underinvestment and gross domestic product losses, which itself reflects increased loss in productivity and reduced labour efficiency in LMICs. Moreover, those regions and subregions showing high prevalence of FGM/C should be the focus of renewed government and donors’ policy efforts. If the goal of public policy is to ensure that the practice is eliminated, further efforts and interventions as well as service planning are urgently needed. This package of comprehensive intervention could include legislation, advocacy, education and multimedia communication, in order to come up with more culturally sensitive and community-engaging strategies such as forging partnership with religious and community leaders, youths and health workers to drive the practice downward.6 16 18 35–41

Strengths and limitations
There are a number of caveats to be considered when interpreting these results. The main limitation of the study is the risk of reporting bias, as with similar studies in this kind; we were unable to deal with bias associated with self-reports.42 This is particularly common in Africa, where there are multiple burden of public health issues including illiteracy, poverty, and communicable and non-communicable diseases.43 It is possible that responses to culturally sensitive issues such as FGM/C will have distorted the findings; it may be under-reported. In fact, a recent body of evidence suggests that under-reporting of FGM/C cases could occur.44 Such an under-reporting may be due to fear that the new legislation banning the practice across many jurisdictions would lead to prosecution of relatives if disclosure was made about their FGM/C status. Another limitation is that we did not consider all the study-level participants’ characteristics, which may have further increased the knowledge of the dynamics of FGM/C practices.

Despite these limitations, the strengths of the study are significant. It is a large, population-based study with national coverage. In addition, the DHS data are widely perceived to be of high quality, as they were based on sound sampling methodology with high response rate. The DHS also adheres to stringent ethical rules in the use is non-commercial. See: http://creativecommons.org/licenses/ by-nc/4.0/.

CONCLUSIONS
The prevalence of FGM/C among children aged 0–14 years varied greatly between countries and regions and also within countries over the survey periods. There is evidence of huge and significant decline in the prevalence of FGM/C among children across countries and regions. There is a need to sustain comprehensive intervention efforts. In addition, further targeted culturally sensitive policy intervention and other effective strategies for preventing FGM/C should be a major public health priority in countries and regions still showing high prevalence of FGM/C among children, where the practice is still pervasive.
