Methods The cross-sectional, mixed methods design was employed. The study population was 785 health care workers and non-health workers working at University of Port-Harcourt Teaching Hospital (Nigeria). The purposive sampling was used for qualitative study while the stratified random sampling technique was utilised for the quantitative study. Qualitative data were collected from fifteen respondents while a total of 511 questionnaires were administered at the study site. The qualitative data was analysed using inductive thematic analysis. The quantitative data was analysed using structural equation modelling (SEM).

Results The qualitative study suggested that quality improvement was perceived as most useful in influencing all the three sub-components of readiness. Training is perceived as most useful in building readiness while it is perceived to be moderately useful in influencing the sub-component of readiness. The OLS estimates indicates that QI/QA exert a positive and significant effect on motivation ($\beta=0.004$, $p<0.05$) and general capacity score ($\beta=-0.28$, $p<0.05$) while it inversely but significantly exerts influence on innovation specific capacity ($\beta=-0.21 \times 10^{-3}$, $p<0.05$). The SEM/pathway analysis shows the direct and indirect routes of interactions among predictors of readiness after adjusting for confounders. All the explanatory variables have significant effect on readiness except gender which was dropped from the final model.

Conclusion The strength of evidence of how an evidence-based system for innovation support can influence readiness was established. Though readiness is a rate-determining step in ensuring robust and effective implementation outcomes for epidemic containment, exploring innovation outcomes and their amplification through explicitly target readiness dynamics requires further investigation.

PO 8356 ANGIogenic and angiostatic factors in the saliva of malaria patients

1Cecilia Lekpor*, 2Felix Batchwy, 3Jonathan Stiles, 4Wilson O Nana. 1Department of Pathology, University of Ghana, Accra, Ghana; 2Morehouse School of Medicine, Atlanta (GA), USA

Background Malaria mortality is associated with exaggerated host responses to inflammatory factors such as C-X-C motif chemokine 10 (CXCL10) and host biomarkers such as angioptin 1 (Ang-1) and angioptin 2 (Ang-2). The aim of this study was to determine saliva levels of CXCL10, Ang-1 and Ang-2 and compare with plasma levels regarding their potential as biomarkers of malaria, which may be useful for further development of highly efficient non-invasive malaria detection methods.

Methods Case control study involving 213 subjects (119 with and 94 without malaria) aged 1–16 years. Haematological determination was done using Haematology Analyser. Plasmodium Lactate Dehydrogenase/Histidine Rich Protein-2 (pLDH/HRP-2) Antigen rapid diagnostic test (RDT) were performed. Plasma and saliva levels of CXCL10, Ang-1 and Ang-2 were measured using Elisa kit. Data was presented as mean ± standard error or median and interquartile range (IQR). A p-value<0.001 was considered statistically significant.

Results There was decreased plasma levels of Ang-1 and increased plasma levels of CXCL10 and Ang-2 in individuals with malaria compared to those without malaria (Ang-1, $p<0.009$; Ang-2, $p<0.001$; CXCL10 $p<0.001$). Biomarker levels in both plasma and saliva in subjects with malaria and without malaria were correlated and a significant relationship was found between Ang –2 and CXCL10 which could be used to predict malaria severity ($p=0.001$ for Ang-2 and $p<0.01$ for CXCL10). Low Ang-1 and high Ang-2 in both plasma and saliva were significantly associated with increased risk of malaria severity: Ang-1, 2741.04 (1785.85–3582.68), $p<0.009$; Ang-2, 3580.82 (2139.61–5091.633.9), $p<0.001$ and Ang-1, 16.98 (10.08–23.76), $p<0.001$ for all). Finally, Ang-2 was informative when combined with CXCL10 to predict malaria severity.

Conclusion These results provide insight into the use of saliva for a non-invasive diagnostic method and demonstrate that Ang-2 combined with CXCL10 is a promising predictive biomarker of malaria severity.

PO 8355 Host genetic polymorphisms and asymptomatic malaria in southern Ghana

1Paulina Otu*, 2Amirata Colle Lo, 3Ben Gyan, 4Yaw Afrane, 5Linda Eva Amoah. 1University of Ghana, Legon, Accra, Ghana; 2Immunology Department, Noguchi Memorial Institute for Medical Research, College of Health Sciences, University of Ghana, Accra, Ghana

Background Despite several interventions through malaria control programmes, asymptomatic malaria is a major barrier to control as asymptomatic individuals serve as reservoirs from which others are re-infected. The mechanism by which these individuals remain asymptomatic is not well understood. Much work has been done in relation to human genes and their association to severe, mild and uncomplicated malaria. However, there is limited knowledge regarding host genetic factors and asymptomatic malaria.

Method In this study, we investigated the association between host genetic polymorphisms of glucose-6-phosphate dehydrogenase gene (G6PD), mannose binding lectin (MBLG54A), tumor necrotic factor alpha (TNF-G308A) and nitric oxide synthase 2 (NOS) (G954C), no significant association was found between these markers and asymptomatic malaria.

Conclusion Upon reviewing our data with other data from published work, we conclude that both heterozygous and hemizygous individuals with G6PD A- and homozygous individuals (GG) of TNF (G308A) polymorphisms could be predisposed genetically to asymptomatic malaria.

PO 8369 Buruli ulcer: pattern of presentation in a Nigerian hospital

1Chukwuonwu Ogbugu*, 2Yeoma Enweani, 3Agu Maurice, 4Ekemchukwu Ogbugu, 5Obiageli Emelumadu. 1Nnamdi Azikiwe University Teaching Hospital, Nnewi, Nigeria; 2Nnamdi Azikiwe University, Anka, Nigeria; 3Nnewi Diocesan Hospital, Nnewi, Nigeria

Background Buruli ulcer is a chronic cutaneous infection caused by Mycobacterium ulcerans, which is on the global list of neglected tropical diseases. Although the pathogen is widely distributed in parts of Africa and South America, the disease is not well documented in Nigeria. This study was undertaken to determine the pattern of presentation of patients with Buruli ulcer.

Methods The study was a retrospective and prospective cross-sectional study conducted at the Department of Pathology, Enugu State University Teaching Hospital (ESUTH), Enugu, Nigeria, from January 2017 to December 2018.

Results A total of 19 patients (age range 18–52 years, mean 31.5 years) with clinical diagnosis of Buruli ulcer were classified into three groups based on their presentation: (I) acute form (9 cases), (II) intermediate form (6 cases), and (III) chronic form (4 cases). The disease was seen more in males (17) and children (14). The most affected site was the limbs (15) and the fewest affected site was the head (4). Most of the patients (15) presented with an ulcerative lesion and the primary location was back, limb and thigh. The mean duration of the lesion before presentation was 7.5 months (range: 1 day–3 years). Only 2 (10.5%) of the patients had history of skin infection due to insect bites, and 18 (94.7%) of patients had positive direct microscopy. The skin was examined for clinical signs of Buruli ulcer to determine the pattern of presentation.
