ABSTRACT
Background COVID-19 impacted global maternal, neonatal and child health outcomes. We hypothesised that the early, strict lockdown that restricted individuals’ movements in Uganda limited access to services.

Methods An observational study, using routinely collected data from Electronic Medical Records, was carried out, in Kawempe district, Kampala. An interrupted time series analysis assessed the impact on maternal, neonatal, child, sexual and reproductive health services from July 2019 to December 2020. Descriptive statistics summarised the main outcomes before (July 2019–March 2020), during (April 2020–June 2020) and after the national lockdown (July 2020–December 2020).

Results Between 1 July 2019 and 31 December 2020, there were 14 401 antenatal clinic, 33 499 deliveries, 111 658 childhood service and 57 174 sexual health attendances. All antenatal and vaccination services ceased in lockdown for 4 weeks.

During the 3-month lockdown, the number of antenatal attendances significantly decreased and remain below pre-COVID levels (370 fewer/month). Attendances for prevention of mother-to-child transmission of HIV dropped then stabilised. Increases during lockdown and immediately postlockdown included the number of women treated for high blood pressure, eclampsia and pre-eclampsia (218 more/month), adverse pregnancy outcomes (stillbirths, low-birth-weight and premature infant births), the rate of neonatal unit admissions, neonatal deaths and abortions. Maternal mortality remained stable. Immunisation clinic attendance declined while neonatal death rate rose (from 39 to 49/1000 livebirths). The number of children treated for pneumonia, diarrhoea and malaria decreased during lockdown.

Conclusion The Ugandan response to COVID-19 negatively impacted maternal, child and neonatal health, with an increase seen in pregnancy complications and fetal and infant outcomes, likely due to delayed care-seeking behaviour. Decreased vaccination clinic attendance leaves a cohort of infants unprotected, affecting all vaccine-preventable diseases. Future pandemic responses must consider impacts of movement restrictions and access to preventative services to protect maternal and child health.

INTRODUCTION
Uganda, as with many nations in the WHO Africa region, has largely avoided the considerable infection rate and death toll from COVID-19 that other nations saw during the first wave,1,2 with 84 116 confirmed cases and 1966 deaths reported as of 6 July 2021.3 While
this is likely under-representative of the true morbidity and mortality,4 Uganda has successfully minimised the spread and direct impact of COVID-19 within its borders through its early, rapid and severe response. However, maternal and child health services were severely impacted by these measures during the height of the lockdown, which may have indirectly affected morbidity and mortality in this group.

Effects of COVID-19
Symptomatic COVID-19 infection in pregnancy is linked to worse maternal and neonatal outcomes than for pregnancies without COVID-19.5,7 Studies across the UK and USA have also shown increased preterm birth, stillbirth, small for gestational age babies and neonatal mortality over the COVID-19 period and in relation to infection in pregnancy.8

However, global estimates of the indirect impacts of COVID-19 could amount to up to a 38.6% increase in maternal mortality, and 44.7% increase in child mortality per month across 118 low and middle-income countries.9 The main factors proposed are disruptions to childbirth services and antenatal care (ANC) such as the management of pre-eclampsia and supplementation advice, wasting and curative child services,9 which the WHO has documented as being affected in many locations.10 Additionally, disruptions to family planning services including access to contraception and safe abortions will result in an additional rise in maternal deaths, abortion-related complications and a large unmet need for contraceptives.11 Further impacts on maternal and child outcomes may be seen through issues surrounding the provision of prevention and management of HIV,9 12 13 reduced lactation support14 and conflicting guidance on whether to avoid breast feeding if infected.15 These impacts have been reported in some low-resource settings globally,10 16 17 particularly with reduced antenatal attendances, linked to transportation restrictions, fear of transmission and lack of antenatal education.17

COVID-19 in Uganda
Preparation and readiness measures against COVID-19 in Uganda began between January and March 2020, focusing on health systems strengthening and capacity building, aided by early allocation of WHO funding.18 19 From 2 March, the public were informed of the threat of COVID-19, with education and training subsequently disseminated.18 Testing focused on contacts of identified cases and those returning from travel, with population-wide lockdown measures imposed quickly after the first case in Uganda was reported on 21 March 2020.20 21 This included border closures, port-of-entry screenings and quarantines for travellers.18 By 25 March, this escalated to a ban on group gatherings and non-essential internal travel, recommendation to work from home and close schools.18 22 The travel restrictions included the cessation of all public transport and a ban on the use of private vehicles without explicit permission to travel.23 At a local level, non-essential visits to Kawempe National Referral Hospital (KNRH) were prohibited for a short time (from 23 March 2020 to 21 April 2020), which included the closure of ANC and childhood immunisation clinics. The Ugandan Ministry of Health (MoH) implemented PCR-based screening for symptomatic patients and any patient who was PCR positive was admitted to a dedicated ward.

This paper aims to quantify the indirect impact of COVID-19 on maternal, neonatal and childhood outcomes at KNRH in Kampala.

METHODS
This was a single-site observational study, which utilised retrospectively collected data, based on KNRH. This is a large, urban hospital with over 21,000 deliveries per annum, 200 antenatal clinic visits and 100 child admissions to hospital per day.24 The hospital provides preventative and curative care during pregnancy and intrapartum, newborn and postnatal care, a paediatric ward and vaccination services at a standard indicative of care in urban Uganda. After the initial lockdown period (4 weeks without outpatient services), measures to reduce the number of women attending ANC included reducing the number of appointments per day from 150 to 90 for ANC and all women <26 weeks gestation being sent away to return after 30 weeks. For infants, the vaccination clinic remained operating routinely. During the initial phases of lockdown (April and May 2020), 35/60 doctors were reassigned to acute care at COVID-19 centres in anticipation of a large number of COVID-19 cases, but 53 nurses were recruited at the same time with result-based financing support raising the number of nurse/midwives on site from 184 to 237 after April 2020.

Patient and public involvement
Patients were not involved directly in the formation of this study. We have involved women in a separate, dedicated qualitative study about their experiences of ANC during the pandemic.25

Data collection
Data were retrospectively collected in January 2021, by hospital staff with access to the Electronic Medical Records (EMR) system. This system is part of the Uganda Ministry of Health (MoH) eHealth Policy, Strategy and Implementation Plan and utilises the District Health Information Software 2 (DHIS2).26 The DHIS2 indicators for which data were collected are detailed in the available data set27 and were taken from health management information system data, which is reported to the MoH, covering pregnancy preventative services, pregnancy curative services, childbirth, care of the newborn, postnatal care, preventative childcare, curative childcare, preventative services for women of reproductive age, curative services for women of reproductive age and unavailability of medicines and commodities. Monthly totals were gathered for the period from July 2019 to December 2020. In accordance with the Sex and Gender
Equity in Research guidelines, pregnancy, childbirth and sexual health-related indicators are reported for those of the female sex, and no segregation is made between male and female sex or gender for childcare indicators as this was not part of the reporting data.26

Neonatal mortality was calculated as the sum of immediate neonatal deaths and deaths from neonatal sepsis 0–7 days, neonatal sepsis 8–28 days, neonatal pneumonia, neonatal meningitis, neonatal jaundice, premature baby (as condition that requires management) and other neonatal conditions.

**Statistical analysis**

Data were input into Microsoft Excel and exported to R V.4.0.4 (R Foundation for Statistical Computing, Vienna, Austria) for further analysis purposes. We calculated the number of attendances per month for each indicator and then analysed the aggregated data at the month level as a proportion of antenatal, labour and delivery, child health or sexual and reproductive health service attendance. For each indicator, the data were divided into pre-COVID (July 2019—March 2020), lockdown (April—June 2020) and post-COVID lockdown (July—December 2020). We used descriptive statistics to summarise demographic and clinical data and present summaries of outcomes before, during and after lockdown (the intervention) as medians and IQRs (online supplemental table 1). To identify suitable regression models for estimating the effects of lockdown, we first graphically plotted the number of events per month over time and assessed for stationarity and autocorrelation using the Durbin-Watson test, graphs of residuals from ordinary least square regression and graphs of auto and partial autocorrelation functions. We then conducted interrupted time series analyses using the generalised least square approach, which allows for inclusion of autoregressive or moving average autocorrelation processes. These models were used to estimate the effects of lockdown on preventative, curative, labour and delivery and child health services at KNRH. The model included a time variable (month), a dummy lockdown variable indicating prelockdown, lockdown and postlockdown and trend variables for the lockdown and postlockdown periods. This approach allows for estimation of the change in levels and trends of the outcomes following the multiple interruptions (start and lifting of lockdown). We use a 5% significance level and 95% CIs.

**RESULTS**

Between 1 July 2019 and 31 December 2020, there were 14 401 ANC attendances, 33 499 deliveries, 111 658 attendances for childhood services and 57 174 sexual and reproductive health (SRH) service attendances at KNRH. There was complete closure of all antenatal, sexual health and vaccination services for the first 4 weeks of the lockdown (from 23 March 2020 to 21 April 2020). An overview of the results of the interrupted time series analysis is displayed in online supplemental table 2.

**Pregnancy**

**Preventative services**

In the 9 months prior to lockdown at the end of March 2020, the median number of attendances for antenatal services was 894 per month (IQR 808–1035). During the 3 months of lockdown, there were 539 fewer visits a month compared with prelockdown (95% CI 195.0 to 516.3; p=0.001). After the lifting of restrictions, the overall trend was for 270 fewer attendances compared with previous periods (95% CI 202.7 to 356.3; p=0.001).

The proportion of women receiving iron supplementation, tetanus vaccination and blood pressure monitoring remained unchanged after the initial closure of services at lockdown, despite fewer women attending ANC (figure 1A–F). However, due to stockouts of intermittent antimalarial prophylaxis and folic acid supplementation prior to lockdown, there was an increase in the proportion of women receiving medication during lockdown.

The proportion of women receiving HIV testing in ANC declined by a rate of 4% (95% CI 1.5% to 6.5% decline; p=0.01) during lockdown but increased back to baseline at the end of restrictions (figure 1G). The median number of women attending prevention of mother-to-child transmission (PMTCT) of HIV services before lockdown was 113 (IQR 56–146). Following the first month of lockdown, during which time the clinic closed, the number of attendances increased slowly with a jump of 85 more visits/month (95% CI 31.6 to 138.4; p=0.009) in the month that lockdown was lifted (figure 1H).

**Curative services**

The median number of women being treated for high blood pressure, pre-eclampsia and eclampsia prior to lockdown was 87/month (IQR 119–241). However, during the 3 months of lockdown, there was a significantly increasing trend of 218 more women/month (95% CI 108 to 327; p=0.002) receiving treatment. There has been a declining trend of 259 women/month (95% CI 153 to 365; p=0.001) receiving treatment in the months since lockdown was lifted. There was no change in the trend of women being treated for bacterial infections throughout the study, although this is incompletely captured in EMR.

**Labour and delivery**

The median number of monthly deliveries was 1869 (IQR 1791–1924) before March 2020 (pre-COVID). At the time of lockdown, there were 320 more deliveries/month (95% CI 199 to 441; p=0.0002). During lockdown, there was a trend of 109 (95% CI 55 to 163; p=0.002) fewer deliveries per month, although delivery trends have increased by a median of 117 (95% CI 54 to 180; p=0.003) deliveries per month since lockdown was lifted. During lockdown, there was an increase in the rate of low-birth weight infants (1.7% increase, 95% CI 0.6% to 2.7%; p=0.011), and in the immediate postlockdown month, an increase in stillbirths (1% increase, 95% CI −2% to 4%; p=0.58) and preterm births (6% increase, 95% CI −3% to 15%; p=0.22), both not significant. There

Interrupted time-series analyses with generalised least square regression for antenatal clinic services. (A) Antenatal clinic (ANC) attendance total attendances and rates of interventions as a proportion of total ANC attendance for: (B) ANC iron administration, (C) ANC folic acid administration, (D) ANC intermittent antimalarial prophylaxis (IPTP) administration, (E) ANC blood pressure measurement, (F) ANC tetanus toxoid administration, (G) ANC HIV testing. (H) Number of women attending prevention of mother to child transmission of HIV (PMTCT) services as part of ANC, before, during and after the COVID-19 lockdown in KNRH. Red dots represent numbers/rates per month. Blue lines connect the red dots to display the observed monthly trend. Red solid lines represent the fitted regression models. Red dashed lines represent the counterfactual scenario.
was no increase in the rates of maternal death over the course of the study (figure 2A–G).

Care of the newborn
Prior to lockdown, there was a median of 700 admissions per month to the neonatal unit (NICU) (IQR 652–706) and a neonatal mortality rate of 39.6/1000 livebirths (IQR 34.6–50.7). During lockdown, there was an increasing rate of NICU admissions of 5.6% (0%–11%; p=0.06). At the end of lockdown, the neonatal mortality rate increased by 10 neonatal deaths per 1000 livebirths/month (IQR 2–10; p=0.001) (figure 3A, B).

Postnatal care
The median number of women receiving immediate postnatal care services (within 24 to 48 hours of delivery) pre-COVID was 1873 (IQR 1823–1993). There were no cases of COVID-19 during this study.

Child health services
Immunisations were offered on all nine scheduled immunisation days in every month in 2019 and 2020. The median number of immunisation clinic attendances in the pre-COVID period was 5871 (95% CI 5643 to 6094). Since the lifting of lockdown, there have been 960 fewer monthly attendances (771 to 2248; p=0.04) (figure 3C). There was no change in the rate of children receiving Bacille Calmette-Guerin (BCG) at birth, oral polio, pneumococcal or rotavirus vaccines since the end of lockdown, although fewer children now attend the immunisation clinic. The increase in the rate of measles vaccine receipt is due to a catch-up campaign after a long stockout (online supplemental figure 1).

There was a decline in the number of children being treated for pneumonia, malaria and diarrhoea (figure 3D–F). There was an increase in the number of children treated for malnutrition after lockdown (online supplemental table 1). We do not have data on infant or child mortality during the period.

Sexual and reproductive health
There was a decrease in the number of women receiving the contraceptive pill (13.6 more women; 95% CI 8.8 to 18.5; p<0.001) after restrictions were lifted. There were no changes to the number of women receiving intrauterine devices, although numbers recorded are small (figure 4A, B). The number of sterilisation procedures and number of women treated for sexually transmitted diseases remained low both pre and postlockdown. The number of abortions and sterilisations related to abortions increased by 338 (95% CI 58 to 619 more procedures; p=0.04) at the start of lockdown.

Availability of medicines
Several shortages were noted in medication and vaccination availability both prelockdown and postlockdown, which may have affected the ability to deliver effective services (figure 5).

DISCUSSION
Despite calls for the prioritisation of antenatal services and the consideration of the indirect impacts of lockdown restrictions on maternal health, the data from our study highlight that maternity, sexual and reproductive health, newborn and child health services were severely affected by COVID-19 restrictions.

Similar to our findings, facilities in rural Uganda saw a drop in antenatal attendances, as have hospitals in Kenya, Ethiopia, Zimbabwe and Rwanda in the first months of the pandemic. The aim of preventative services is to reduce maternal and newborn morbidity and mortality and any reduction in their availability can give an indication of the potential longer term impacts—including increased rates of maternal anaemia, puerperal sepsis, stillbirth, low birth weight, preterm birth, malaria infection, pre-eclampsia/eclampsia, mother to child transmission of HIV and neonatal tetanus. Our study did not see an increase in maternal mortality despite fewer ANC attendances. This could be due to more women delivering in the community, as has been reported elsewhere, however, our delivery rates remained constant throughout the period of study, suggesting that there may be alternative reasons for these findings, including increased maternal and neonatal morbidity, rather than mortality.

There are many proposed reasons why the ANC service and immunisation clinic attendances decreased so drastically during the lockdown. The national guidance at the start of the pandemic resulted in the closure of public transport, which a large proportion of patients rely on to access healthcare facilities, hence impacting their physical ability to access care, as has been reported in Uganda and in other countries. Other themes which have been reported to have affected attendances are the lack of healthcare staff, fear of infection, disruption of services due to COVID-19, lockdown orders restricting movement and the increased price of transport. These themes have been highlighted in other studies in the region, indicating the need to consider the implications of lockdown measures on public confidence in healthcare in future emergencies. The impacts of such public health measures must also be considered as to how they impact within different socioeconomic contexts, as changes to service use during the pandemic have not been universal, impacting more on those in lower socioeconomic circumstances.

While the number of ANC visits decreased, our delivery rate did not decline by the same amount. Kawempe hospital caters for a population of 2 million people, yet the number of women attending four ANC visits remains below 90%, although the majority of women in Kampala still deliver in hospital (94%). This data suggest that ANC and hospital delivery are not seen as a continuum of care in our setting and could account for the phenomenon of increased deliveries despite fewer ANC visits. Alternatively, fear of contracting COVID-19 in...
Figure 2  Labour and delivery indicators for Kawempe National Referral Hospital (KNRH), July 2019 to December 2020. Interrupted time-series analyses with generalised least square regression for (A) total deliveries, (B) caesarean sections, (C) haemorrhage related to labour and delivery, (D) maternal mortality, expressed as rate per 100 000 maternities, (E) stillbirth rate as a percentage of deliveries, (F) preterm birth rate as a percentage of total livebirths, (G) low birth weight as a percentage of total livebirths, before, during and after the COVID-19 lockdown in KNRH. Red dots represent numbers/rates per month. Blue lines connect the red dots to display the observed monthly trend. Red solid lines represent the fitted regression models. Red dashed lines represent the counterfactual scenario.
the community may have influenced the decision to give birth in a hospital environment.

The COVID-19 pandemic has impacted on childbirth and deliveries across the region, with some reports of decreased hospital deliveries. Facilities in Kenya have reported an increase in the number and rate of C sections and stillbirths, increased PPH and an increase in maternal deaths, disproportionately affecting adolescents. While an increase in stillbirth and preterm birth was seen in our population at the end of lockdown, this was not significant. The age of the pregnant woman was not included in our data set and may shed valuable light on any population-level disparities in outcomes. Similar to other studies from Africa, we advocate for prioritising safe and effective antenatal, intrapartum and postnatal care in future health emergencies.

The rise in neonatal deaths, low-birth-weight babies and NICU admissions are likely a result of the lack of

![Figure 3](image-url)
ANC from March to May. Sudden sharp changes in neonatal outcomes have been reported in South Africa, where an increase in neonatal mortality was linked to the disruption of services and diversion of resources due to COVID-19 necessities. As seen with our data, a hospital in Malawi found an increase in babies born earlier and at lower birth weights, however, the same study did not find this in a Zimbabwean hospital, suggesting there are differences between countries that remain unexplained.

A decrease in children attending hospital, as seen in our findings, was also seen in South Africa and Ethiopia. This is likely also associated with fear of attending healthcare settings, inaccessibility, and a reduction in self-referrals, as seen with ANC. Conversely, there was an increase in malnutrition attendances, likely due to the societal impacts of COVID-19 restrictions on child health and nutrition. The lack of therapeutic foods available may have been affected by border closures and trade restrictions, in a similar manner to medication availability in Nigeria.

The reduction in immunisation clinic attendances in our cohort puts an estimated 20,000 children at risk of mortality from vaccine-preventable diseases such as tetanus and polio. Uganda was declared polio-free in September 1, 2021 by guest. Protected by copyright.
2010.\textsuperscript{31} However, the situation remains precarious due to the possibility of imported virus from surrounding countries where polio is not yet eradicated.\textsuperscript{32} The likelihood of a potential infectious disease outbreak can be predicted based on the proportion of coverage lost by a period of reduction in immunisations, and The WHO estimates that at least 80 million children will be at risk of diseases like tetanus, polio, diphtheria and measles due to disruption of vaccination programmes during the pandemic.\textsuperscript{33} A reduction in the uptake of childhood immunisations was also seen in England,\textsuperscript{54} Singapore\textsuperscript{55} and Brazil\textsuperscript{56} at the start of the pandemic, highlighting the universal impact of COVID-19 on child health. The follow-up response to vaccine catch-up in this pandemic is of key importance in mitigating future outbreaks and further impacts on child health.\textsuperscript{57\textsuperscript{58}}

While our data show some resiliency in sexual health and contraceptive services, the reduction in HIV clinical attendances is worrying and requires further outreach work to ensure the provision of care. PMTCT services bounced back quickly, in part due to international funding support mechanisms in place, such as that from United States Agency for International Development (USAID).\textsuperscript{59} Sexual and reproductive health services have also been impacted across other East African nations. Facilities in Kenya and Ethiopia reported that contraceptive services were limited and decreases were seen in family planning attendances due to the closure of services,\textsuperscript{34\textsuperscript{39}} although national data from Kenya show no change overall in the usage of services.\textsuperscript{36}

Clinical and research implications

While the effects of COVID-19 are wide ranging, the continuation of changes to antenatal services, maternal and neonatal outcomes and reduced number of children being treated for pneumonia and malaria in hospital through to December 2020 may also be influenced by other social factors. Many staff and patients were affected by restrictions to movement in October and November 2020 due to political campaigning and riots relating to the presidential elections. This highlights the susceptibility of health and healthcare services to wider events, reinforcing the need for resilience and planning going forward.

Strengths and limitations

Although the limitations of this study lie in the use of data from a single site, collected retrospectively, this has allowed the inclusion of over 33 000 births, 14 401 antenatal attendances and 111 658 childhood immunisations, highlighting the massive impact on this population. Furthermore, the use of data from EMR rather than direct patient records mean these data are likely an under-representation of the true values of each indicator. Statistical comparison using data from the full year of 2019 would have enabled a better understanding of how 2020 compared with the time before COVID-19. Even with these documented limitations, our findings reinforce the importance of considering maternal and child health in future pandemic responses.

CONCLUSIONS

Maternal, neonatal, child and sexual and reproductive health services were all impacted by the restrictions imposed by the Ugandan government in response to COVID-19. Our results demonstrate the urgent need for pandemic responses that take into account the local context, where a stringent lockdown may be detrimental to the overall health of the population. Such responses must include the prioritisation of preventative care, including maintaining antenatal clinic visits, child health and vaccination services to prevent delayed impacts on maternal, neonatal and child health. Furthermore, any disruptions to immunisation schedules must be mitigated as rapidly as possible, to prevent further infectious disease outbreaks and future pandemics.
